

# Even Tree

You are given a tree (a simple connected graph with no cycles).

Find the maximum number of edges you can remove from the tree to get a **forest** such that each connected component of the forest contains an even number of nodes.

As an example, the following tree with **4** nodes can be cut at most **1** time to create an even forest.

## Function Description

Complete the `evenForest` function in the editor below. It should return an integer as described.

`evenForest` has the following parameter(s):

- `t_nodes`: the number of nodes in the tree
- `t_edges`: the number of undirected edges in the tree
- `t_from`: start nodes for each edge
- `t_to`: end nodes for each edge, (Match by index to `t_from`.)

## Input Format

The first line of input contains two integers  $t\_nodes$  and  $t\_edges$ , the number of nodes and edges.  
The next  $t\_edges$  lines contain two integers  $t\_from[i]$  and  $t\_to[i]$  which specify nodes connected by an edge of the tree. The root of the tree is node **1**.

## Constraints

- $2 \leq n \leq 100$
- $n \in \mathbb{Z}_{\text{even}}^+$

*Note:* The tree in the input will be such that it can always be decomposed into components containing an even number of nodes.  $\mathbb{Z}_{\text{even}}^+$  is the set of positive even integers.

## Output Format

Print the number of removed edges.

## Sample Input 0

```
10 9
2 1
3 1
4 3
5 2
6 1
7 2
8 6
9 8
10 8
```

## Sample Output 0

**Explanation 0**

Remove edges  $(1,3)$  and  $(1,6)$  to get the desired result.

.

**Original tree****Decomposed tree**

No more edges can be removed.
