

# Cut Tree

Given a tree  $T$  with  $n$  nodes, how many subtrees ( $T'$ ) of  $T$  have at most  $K$  edges connected to  $(T - T')$ ?

## Input Format

The first line contains two integers  $n$  and  $K$  followed by  $n-1$  lines each containing two integers  $a$  &  $b$  denoting that there's an edge between  $a$  &  $b$ .

## Constraints

$1 \leq K \leq n \leq 50$

Every node is indicated by a distinct number from 1 to  $n$ .

## Output Format

A single integer which denotes the number of possible subtrees.

## Sample Input

```
3 1
2 1
2 3
```

## Sample Output

```
6
```

## Explanation

There are  $2^3$  possible sub-trees:

$\{\}$   $\{1\}$   $\{2\}$   $\{3\}$   $\{1, 2\}$   $\{1, 3\}$   $\{2, 3\}$   $\{1, 2, 3\}$

But:

the sub-trees  $\{2\}$  and  $\{1,3\}$  are not valid.  $\{2\}$  isn't valid because it has 2 edges connecting to it's complement  $\{1,3\}$  whereas  $K = 1$  in the sample test-case  $\{1,3\}$  isn't valid because, well, it's not a sub-tree. The nodes aren't connected.
